

Comparing GUI and CLI

The graphic user interface (GUI) and the Command-Line interface are two very different ways to access and communicate with your computer system. The more commonly used interface being the GUI is what someone would be interacting with when using their system. The GUI is the visual interface you use to do basic tasks. On the other hand the CLI can be considered as a much more complex interface. The CLI is completely text based and uses a prompt to execute commands. The user has to type specific commands to achieve their goals.

Although the GUI is more notable, the CLI has been around for much longer. The GUI is very beginner friendly and easy to understand, while the CLI can be described as learning a whole new language. The CLI is used to give the user complete access to a system's abilities. The GUI and CLI have major differences but without one or the other simply using a computer would not be the same.
